1 Introduction

Artificial Intelligence (AI) is transforming the global labor market by reshaping job roles, required skills, and employment opportunities. While some occupations are expanding due to technological advancement, others are declining as automation replaces repetitive and routine tasks. This transformation creates uncertainty for students, job seekers, organizations, and policymakers.

This report presents key insights derived from interactive Power BI dashboards developed for the AI Job Market Business Intelligence project. The objective is to translate data into actionable insights that support career planning, workforce strategy, and policy formulation.

2 Key Findings and Interpretation

2.1 Overall Job Growth Remains Positive

The analysis shows a total net job increase of approximately one million jobs between 2024 and 2030. Increasing jobs significantly outweigh decreasing jobs, indicating that AI-driven transformation leads to net job creation rather than destruction.

Why this matters: This finding challenges the perception that AI mainly eliminates jobs. Instead, AI restructures employment, emphasizing adaptation and skill development.

Figure 1: Total Net Job Change by Job Status

2.2 Moderate Automation Risk Across Jobs

The average automation risk across jobs is approximately 50%, indicating partial task automation rather than full job replacement.

Why this matters: Jobs are evolving rather than disappearing, making reskilling and AI-human collaboration critical for future employability.

2.3 Geographic Differences in AI Impact

Countries such as the USA, Canada, the UK, China, and India show positive net job growth, while Germany and Brazil experience net job declines, despite similar automation risk levels.

Why this matters: Automation risk alone does not determine employment outcomes. National labor policies and education systems strongly influence resilience.

Figure 2: Geographic Distribution of Job Growth and Automation Risk

2.4 Education Level and Job Vulnerability

Jobs requiring advanced education (Master's and PhD) show positive net job growth and lower automation risk, while Bachelor's and Associate degree roles are more vulnerable.

Why this matters: Education remains a protective factor, but relevance and specialization are increasingly important.

2.5 Career Stability and Salary Do Not Always Move Together

The dashboards show that some highly stable careers also offer strong salaries (such as Water Quality Scientist and Geologist), while other stable careers maintain only moderate salary levels (such as Writer, Youth Worker, and Web Designer). At the same time, some higher-paying roles do not rank among the most stable careers.

Why this matters: Salary alone is not a reliable indicator of long-term career safety. Combining salary, career stability, automation risk, and projected job growth provides a more realistic basis for career planning.

Figure 3: Career Stability Index and Median Salary by Job Title

2.6 Industry-Level Opportunities and Risks

Manufacturing and Entertainment show the highest projected job openings by 2030. However, some high-growth industries, such as Transportation, also exhibit high automation risk and moderate remote work readiness.

Why this matters: Industry growth alone does not guarantee job security. A multidimensional evaluation is necessary for informed decision-making.

2.7 Average Remote Work Ratio

Manufacturing and healthcare surprisingly lead in average remote work potential (above 50%), while sectors such as Finance and IT lag behind at approximately 49%.

Why this matters: Remote work potential is no longer exclusive to digital industries. Manufacturing and healthcare benefit from automation and remote system monitoring, while finance remains constrained by regulatory, security, and human-interaction requirements that limit full remote scalability.

3 Business Recommendations

- Policymakers should implement targeted reskilling programs for industries and regions experiencing job decline due to automation and structural change.
- Students should prioritize careers with high Career Stability Index and High-Opportunity Career Score rather than salary alone.
- Universities should redesign curricula to integrate AI literacy and future-proof skills across all disciplines.

- Industry leaders should focus on AI adoption that complements human skills rather than replaces them.
- Healthcare workforce expansion should be prioritized by investing in AI tools that augment healthcare workers while preserving human-centered care.
- Organizations should redirect PhD talent toward AI governance, oversight, and strategic decision-making roles.
- Universities and training institutions should create transition pathways for bachelor-level professionals in declining roles.
- Organizations should adjust salary structures to retain essential, high-stability roles critical to public and economic well-being.

4 Limitations and Future Improvements

4.1 Limitations

- The analysis relies on projected data rather than real-time labor market observations.
- Country-level aggregation may hide important regional variations.
- AI impact indicators are estimated rather than directly measured.
- Demographic factors are only partially represented, limiting deeper socio-economic analysis.

4.2 Future Improvements

- Integrate real job-posting data to reflect live labor market demand.
- Apply time-series analysis to capture long-term employment trends.
- Incorporate skill-level automation metrics for finer-grained analysis.
- Use forecasting models to predict future job demand beyond static projections.
- Expand demographic and geographic variables to strengthen policy relevance.
